# Operating Systems – COC 3071L SE 5th A – Fall 2025

### Lab 5: Introduction to Threads

### 1. Introduction to Threads

#### 1.1 What is a Thread?

A **thread** is the smallest unit of execution within a process.

- A process can have multiple threads running concurrently
- All threads within a process share:
  - Memory space (code, data, heap)
  - File descriptors
  - Process ID
- Each thread has its own:
  - Thread ID (TID)
  - Stack
  - Program counter
  - Register set

#### Real-world analogy:

- Process = A restaurant kitchen
- Threads = Multiple cooks working together in the same kitchen, sharing ingredients and equipment

# 1.2 Threads vs Processes – Quick Comparison

		•
Feature	Process	Thread
Memory	Separate memory space	Shared memory space
Creation	Expensive (fork)	Lightweight (pthread_create)
Communication	IPC needed (pipes, etc.)	Direct (shared variables)
Context Switch	Slower	Faster
Independence	Fully independent	Dependent on parent process

#### When to use threads?

- When tasks need to share data frequently
- For parallel execution within the same application
- When you need lightweight concurrency

# 2. POSIX Threads (pthreads) Library

In Linux, we use the **POSIX threads (pthreads)** library for thread programming.

# 2.1 Compilation Requirements

When compiling programs with threads, you **must** link the pthread library:

```
gcc program-c -o program -lpthread
```

The -Ipthread flag links the pthread library.

# 3. C Programs with Threads

### **Program 1: Creating a Simple Thread**

**Objective:** Create a thread and print messages from both main thread and new thread.

```
#include <stdio.h>
#include <pthread.h>
#include <unistd.h>

// Thread function - this will run in the new thread
void* thread_function(void* arg) {
    printf("Hello from the new thread!\n");
    printf("Thread ID: %lu\n", pthread_self());
    return NULL;
}

int main() {
    pthread_t thread_id;

    printf("Main thread starting...\n");
    printf("Main Thread ID: %lu\n", pthread_self());

    // Create a new thread
    pthread_create(&thread_id, NULL, thread_function, NULL);
```

```
// Wait for the thread to finish
pthread join(thread_id, NULL);

printf("Main thread exiting...\n");
return 0;
}
```

```

                                                                  Q Search
```

```
gcc thread1-c -o thread1 -lpthread
./thread1
```

### **Explanation:**

```
pthread_t thread_id
```

This creates a **variable** to hold the thread's ID (like a file descriptor or process ID). It's just a handle the OS uses to manage the thread.

```
pthread_create(&thread_id, NULL, thread_function, NULL)
```

Let's decode the four parameters:

Parameter	Туре	Meaning
&thread	pthread_t*	Where the new thread ID will be stored
NULL	pthread_attr_t*	Thread attributes (priority, stack size, etc.)  — NULL means default

myThread	<pre>void* (*start_routine) (void*)</pre>	Function to run in the new thread
NULL	void*	Pointer passed to the function for data

<sup>•</sup> pthread\_join() → Waits for thread to finish (like wait() for processes)

### **Program 2: Passing Arguments to Threads**

Objective: Pass data to a thread function.

```
#include <stdio.h>
#include <pthread.h>
void* print number(void* arg) {
   // We know that we've passed an integer pointer
    int num = *(int*)arg; // Cast void* back to int*
   printf("Thread received number: %d\n", num);
   printf("Square: %d\n", num * num);
   return NULL;
}
int main() {
   pthread_t thread_id;
   int number = 42;
   printf("Creating thread with argument: %d\n", number);
   // Pass address of 'number' to thread
    pthread_create(&thread_id, NULL, print_number, &number);
   pthread_join(thread_id, NULL);
   printf("Main thread done.\n");
   return 0;
}
```

pthread\_self() → Returns the thread ID of calling thread

```

```

```
gcc thread2.c -o thread2 -lpthread
./thread2
```

#### **Important Notes:**

- The 4th argument of pthread\_create() is passed to the thread function
- It's a void\* pointer, so you can pass any data type
- Remember to cast it properly inside the thread function

Here's what happens step by step:

```
int value = *(int*)arg;
```

- 1. (int\*)arg cast void\* back to int\*.
- 2. \*(int\*)arg dereference the pointer to get the integer value it points to.

### Why use void\*

The thread function must have the **standard signature**:

```
void* function name(void* arg)
```

That's because threads can accept *any* data type — integers, structs, arrays, etc. void\* acts like a universal pointer type.

If you need to pass multiple variables, you wrap them in a struct and pass a pointer to it.

# **Program 3: Passing Multiple Data**

```
#include <stdio.h>
#include <pthread.h>
typedef struct {
   int id;
   char* message;
} ThreadData;
void* printData(void* arg) {
   ThreadData* data = (ThreadData*)arg;
   printf("Thread %d says: %s\n", data->id, data->message);
   return NULL;
}
int main() {
   pthread_t t1, t2;
   ThreadData data1 = {1, "Hello"};
   ThreadData data2 = {2, "World"};
   pthread_create(&t1, NULL, printData, &data1);
   pthread_create(&t2, NULL, printData, &data2);
   pthread_join(t1, NULL);
   pthread_join(t2, NULL);
   printf("All threads done.\n");
   return 0;
}
```

```
gcc thread3-c -o thread3 -lpthread
./thread3
```

# **Program 4: Thread Return Values**

Objective: Get return values from threads.

```
#include <stdio.h>
#include <pthread.h>
#include <stdlib.h>
void* calculate_sum(void* arg) {
   int n = *(int*)arg;
   int* result = malloc(sizeof(int)); // Allocate memory for result
   *result = 0;
   for (int i = 1; i <= n; i++) {
       *result += i;
   }
   printf("Thread calculated sum of 1 to %d = %d\n", n, *result);
   return (void*)result; // Return the result
}
int main() {
   pthread_t thread_id;
   int n = 100;
   void* sum;
   pthread_create(&thread_id, NULL, calculate_sum, &n);
   // Get the return value from thread
   pthread_join(thread_id, &sum);
   printf("Main received result: %d\n", *(int*)sum);
   free(sum); // Don't forget to free allocated memory
   return 0;
}
```

```

#### **Key Points:**

- Thread functions return void\*
- Use pthread\_join() to retrieve the return value
- Remember to free any dynamically allocated memory

# 4. Basic Multithreading

### 4.1 What is Multithreading?

- **Multithreading** means running multiple threads *concurrently* to perform different tasks within the same process.
- It allows:
  - Faster program execution on multi-core CPUs
  - Better resource utilization
  - Improved responsiveness (e.g., in GUIs or servers)

#### Example use cases:

- A web server handling multiple client requests simultaneously
- A program performing computation and I/O in parallel

# **Program 1: Creating and Running Multiple Threads**

#### Objective:

Create multiple threads that execute independently and print messages concurrently.

```
#include <stdio.h>
#include <pthread.h>
#include <unistd.h>
void* worker(void* arg) {
   int thread_num = *(int*)arg;
   printf("Thread %d: Starting task...\n", thread_num);
   sleep(1); // Simulate some work
   printf("Thread %d: Task completed!\n", thread_num);
   return NULL;
}
int main() {
   pthread_t threads[3];
   int thread_ids[3];
   for (int i = 0; i < 3; i++) {
        thread_ids[i] = i + 1;
        pthread_create(&threads[i], NULL, worker, &thread_ids[i]);
   }
   for (int i = 0; i < 3; i++) {
        pthread join(threads[i], NULL);
    }
    printf("Main thread: All threads have finished.\n");
   return 0;
}
```

```

                                                                    👛 🖿 🗓 🐧 🌀 🥳 🧖 💆 📆 🐞
                                    Q Search
```

```
gcc multithread_basic-c -o multithread_basic -lpthread
./multithread_basic
```

#### **Explanation:**

- Three threads execute the same function concurrently.
- Output order may vary because threads run in parallel.
- Demonstrates basic multithreading behavior and non-deterministic execution order.

### **Program 2: Demonstrating a Race Condition**

**Objective:** What happens when multiple threads modify a shared variable **without synchronization**.

```
#include <stdio.h>
#include <pthread.h>
int counter = 0; // Shared variable
void* increment(void* arg) {
   for (int i = 0; i < 100000; i++) {
        counter++; // Not thread-safe
   return NULL;
}
int main() {
   pthread_t t1, t2;
    pthread_create(&t1, NULL, increment, NULL);
    pthread_create(&t2, NULL, increment, NULL);
   pthread_join(t1, NULL);
   pthread_join(t2, NULL);
   printf("Expected counter value: 200000\n");
   printf("Actual counter value: %d\n", counter);
   return 0;
}
```

```
gcc race_condition.c -o race_condition -lpthread
./race_condition
```

#### Observation:

- The final counter is often less than 200000.
- This happens because both threads read and write counter simultaneously a race condition.

#### **Concept introduced:**

When multiple threads access shared data without control, results become unpredictable.

Synchronization will be used to solve this.
